Population and Food Production in Karamoja

Indipendent project 2

by Angela Chesire

Contents

01. Introduction

02. Objectives

03. Relationship insight

04. Key findings

05. Conclusion and Recommendations

PART ONE

Introduction

This project analyzes the relationship between population and food production across districts in Karamoja using maize and sorghum data.

- Maize and Sorghum Production
    - Examines production levels across different districts in Karamoja
    - Population Distribution
    - Analyzes how population varies across districts
    - Relationship Analysis
    - Explores the correlation between population size and total food production

PART TWO

Objectives

Compare crop production across districts

Crop production level

Compare maize and sorghum production across districts

- Identify districts with highest and lowest production

District performance

Analyze how production differs between districts

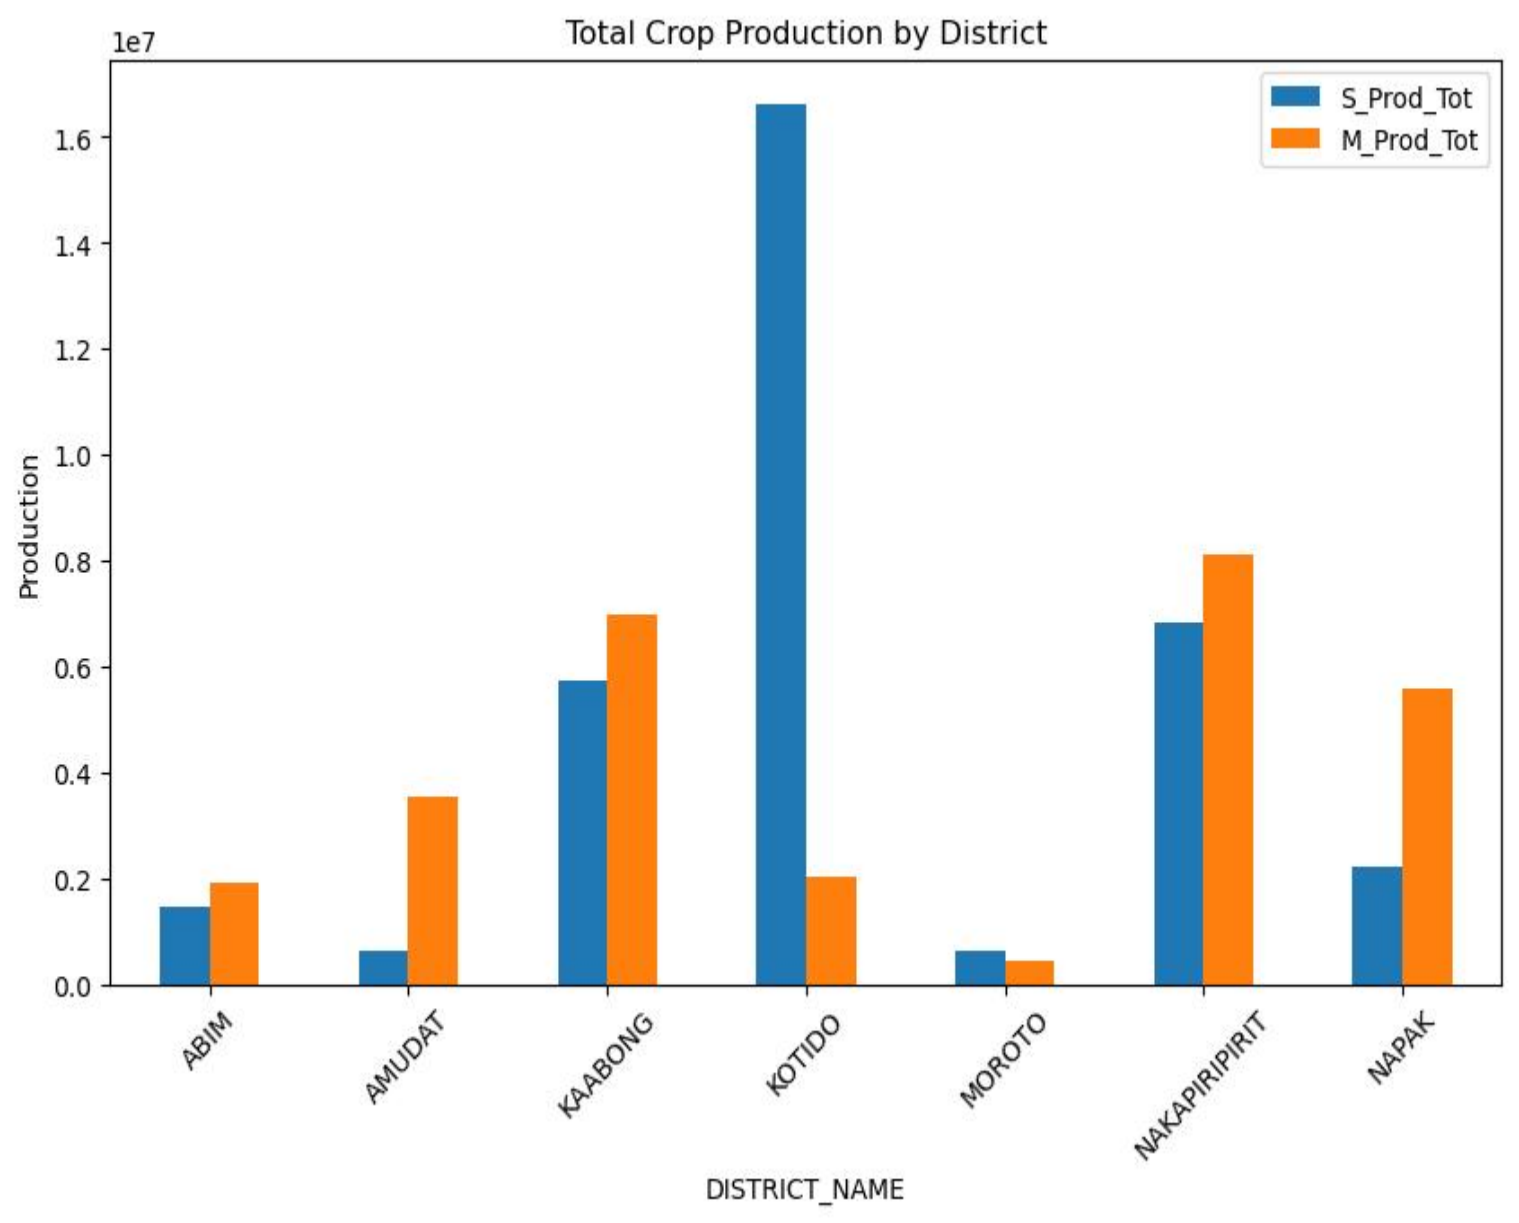
- Highlight areas with strong vs weak agricultural output

Production comparisons

Compare maize vs sorghum contribution to total production

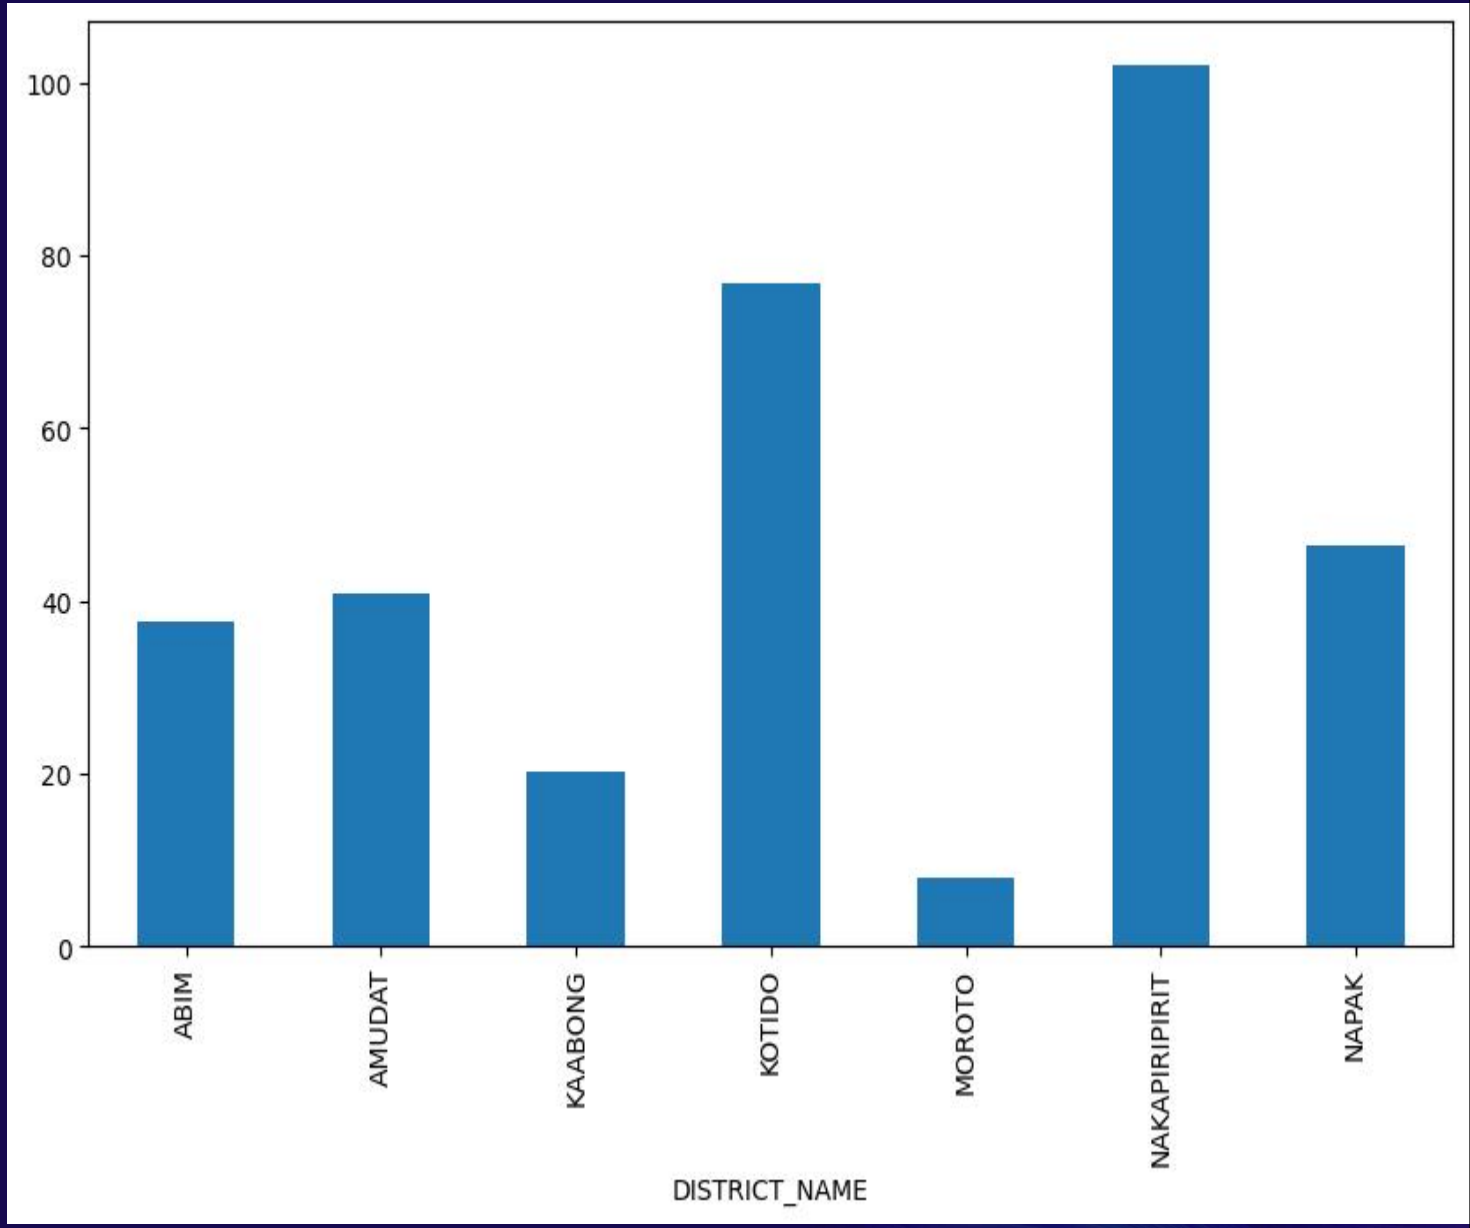
- Identify which crop dominates in each district

Crop prroduction comparison



Kotido has the highest production
Moroto has the lowest production
Other districts show moderate production levels

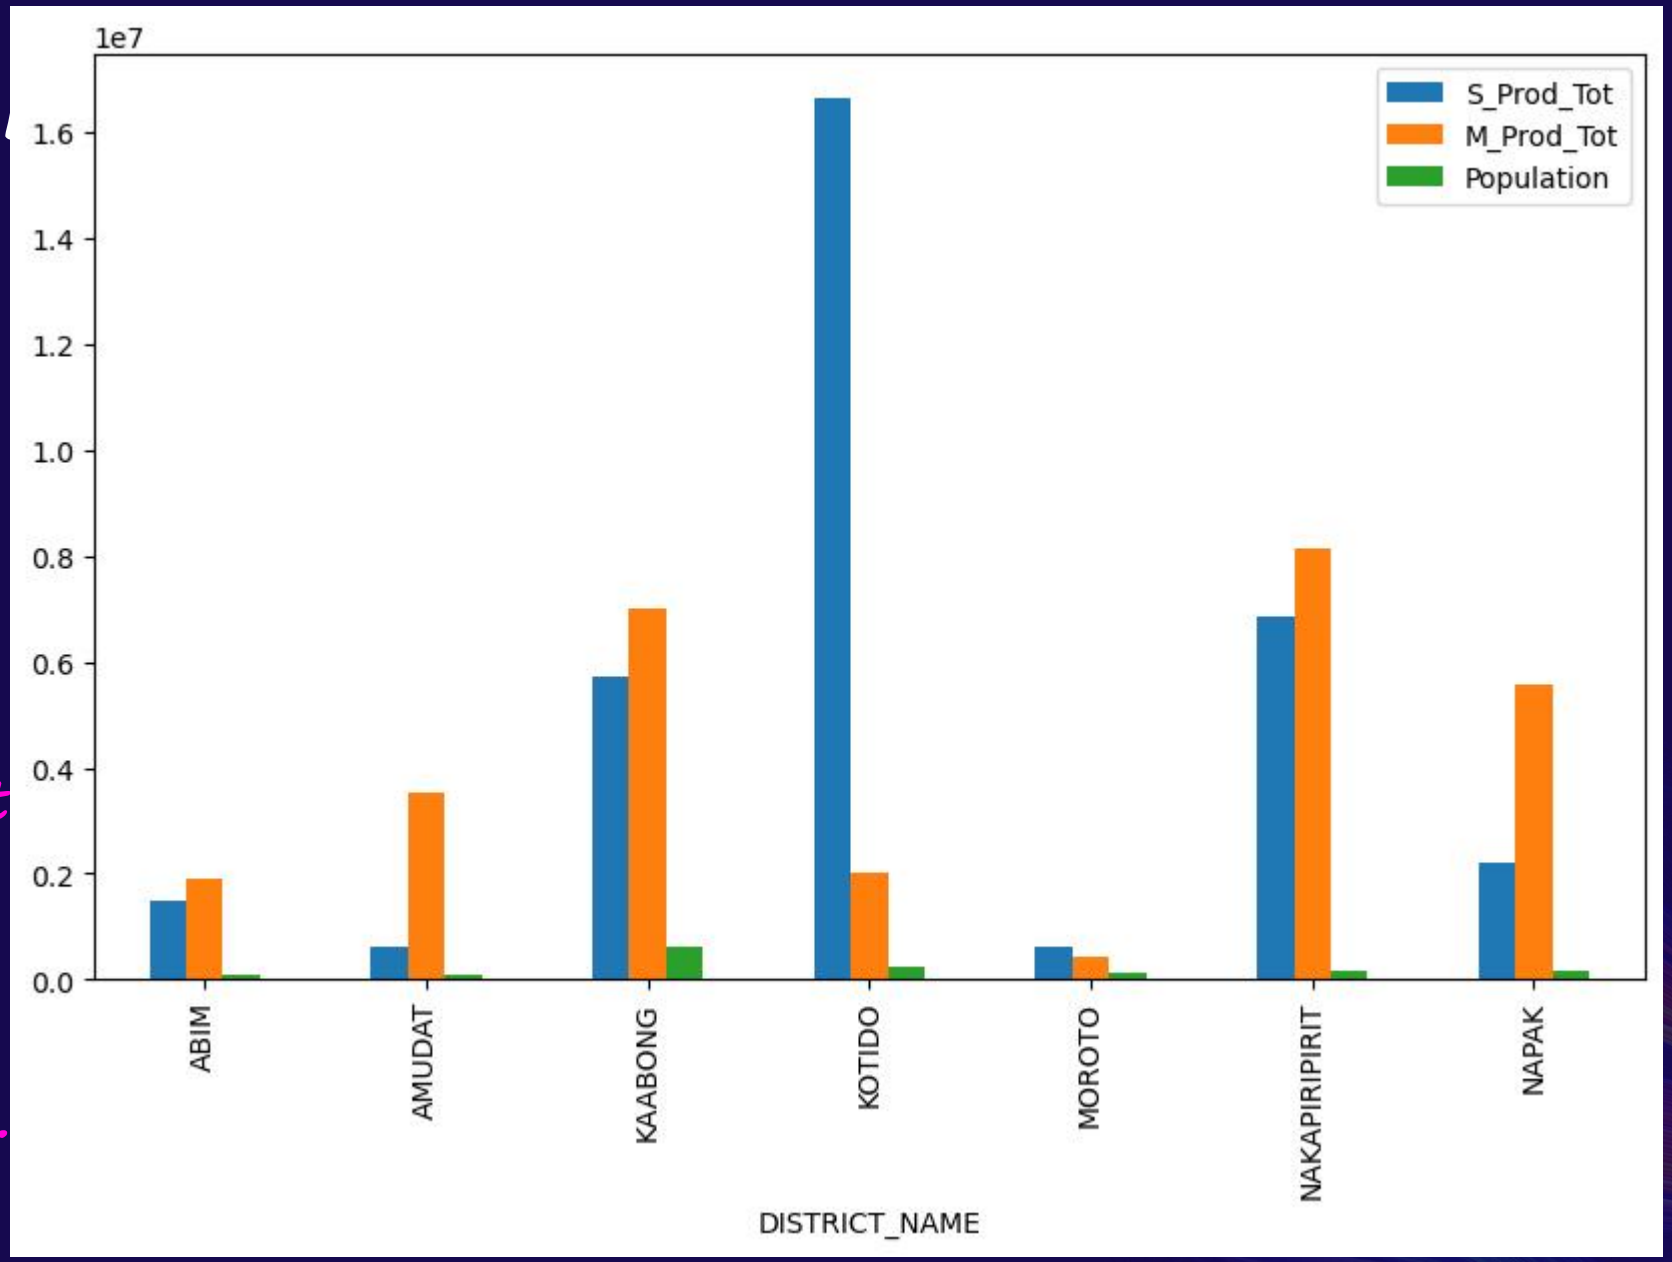
Population vs Total production



- There is a positive relationship between population and total production.
- Districts with higher population generally show higher production.
- However, some districts have relatively high population but lower production levels.
- This suggests imbalance between population size and production capacity.

Production by person

Nakapiripirit and Napak have higher production per person.
- Kotido has high total production but lower production per person due to its larger population.
- Moroto has the lowest production per person.
- This indicates differences in how effectively production supports the population.



PART THREE

Key Findings

Key findings

- - Food production is unevenly distributed across districts.
- - High total production does not always translate to high production per person.
- - Population size influences production, but does not fully determine it.
- - Some districts may be at risk of lower food availability compared to others.

PART FIVE

Conclusion and Recommendations

Conclusion and Recommendations

- There are clear disparities in production and population across districts.
- Efforts should focus on improving production in low-performing districts such as Moroto.

- Increasing efficiency in districts with high population can improve food availability per person.
- Better resource allocation and agricultural support can help balance production across the region.

Thank You
